## 10 HOTTEST GLOBAL YEARS ON RECORD

+1.4°C 2.52°F

Source: NASA GISS & NOAA NCEI global temperature anomalies averaged and adjusted to early industrial baseline (1881-1910). Data as of 1/12/2023.

CLIMATE CENTRAL

#1 OR, WA, #2 ID

# Observed temperatures: NW is also warmer

Since 1895, average temperature has increased almost 2°F

Northwest Average Temperature  
January-December

# Observed temperatures: NW is also warmer

Higher minimum temperatures: longer frost-free season

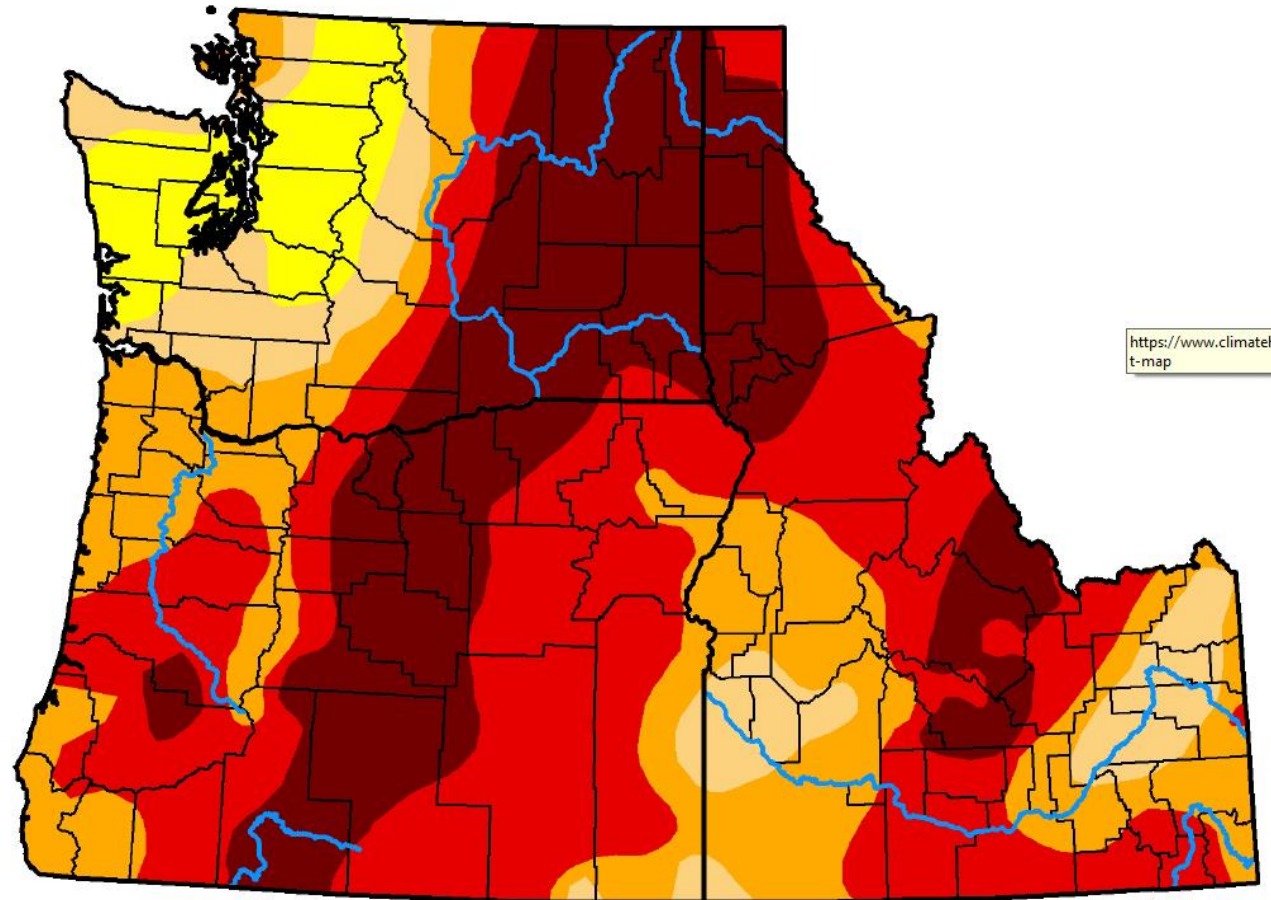

## Northwest Minimum Temperature

January-December

# U.S. Drought Monitor – 24 August 2021

## Drought Classification

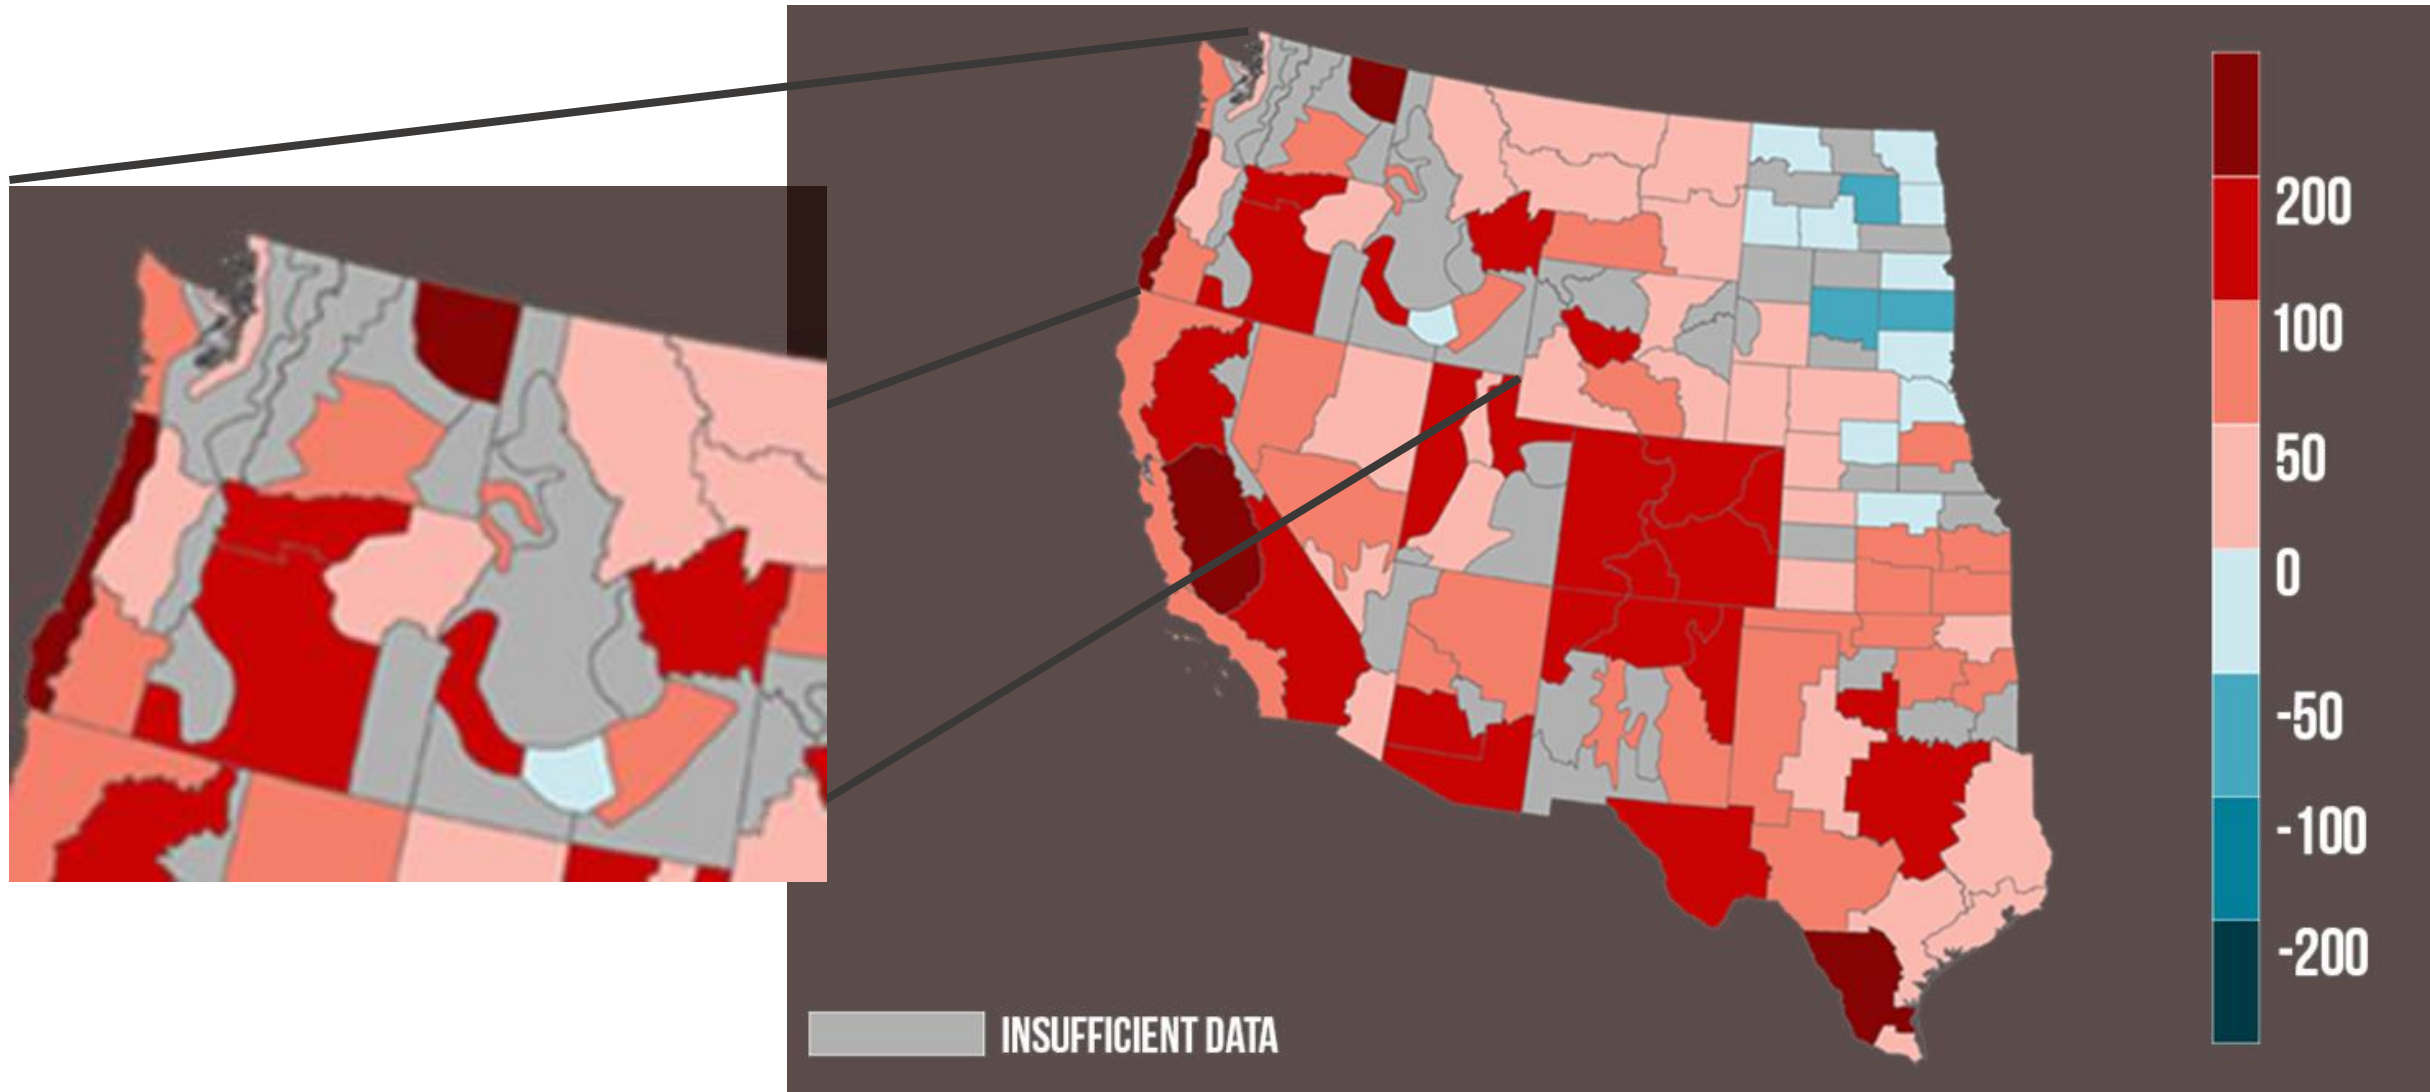

# Firmageddon?!

# Change in fire weather days

(% change from 1973 to 2020)

# Wildfire area burned in the U.S.

# Wildfires are reburning areas more frequently

## Southwest Washington

Fires have burned  
some areas 3 times  
since 2008

Map by R. Norheim

# Interacting disturbances?

## Recent Disturbance

Fire area  
(since 1984)

Insect and  
disease area  
(since 1997)

# Projected temperatures

High emissions greenhouse gas scenario (RCP 8.5), project annual average temperature to increase by 11 °F by the 2080s

# Projected precipitation

# Snowpack Sensitivity

Percent Change  
April 1 SWE

3°C temperature increase

# How will trees grow in a warmer climate?

## Eastside coniferous forest

*Moisture limited*

Growth will decrease:

- Ponderosa pine
- Douglas-fir
- Western larch
- White fir/grand fir

# How will trees grow in a warmer climate?

## Low elevation, westside forest

*Moisture limited*

Growth will decrease:

- Douglas-fir
- Western hemlock
- Western redcedar
- Sitka spruce

# How will trees grow in a warmer climate?

## High-elevation coniferous forest

*Energy limited*

Growth will increase:

- Subalpine fir
- Mountain hemlock
- Lodgepole pine

# How will trees grow in a warmer climate?

**Riparian areas, wetlands,  
groundwater-dependent systems**

*Water controlled*

Growth and regeneration will change:

- Species composition
- Fire susceptibility

# Extreme weather + increased disturbance: Our primary challenge

# Climate change affects insects

*Mountain pine beetle (MPB)*

Warmer temperature has favored MPB by:

- Increasing its reproductive rate
- Allowing an expanded geographic range

*Several weeks of high temperature and low rainfall are sufficient to dry fuels and cause extreme fire hazard.*

Increasing air temperature

+

Decreasing summer rain

+

Earlier snowmelt

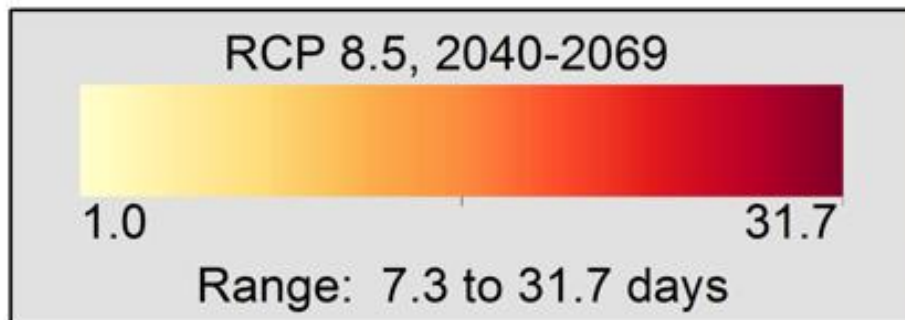

LEAD TO DRIER  
FUELS & FORESTS

Earlier and longer periods  
of dry fuels are affected by  
multiple factors

# More “very high” fire danger days

*Mid 21<sup>st</sup> century*

Increase in Very High Fire Danger Days

early-century

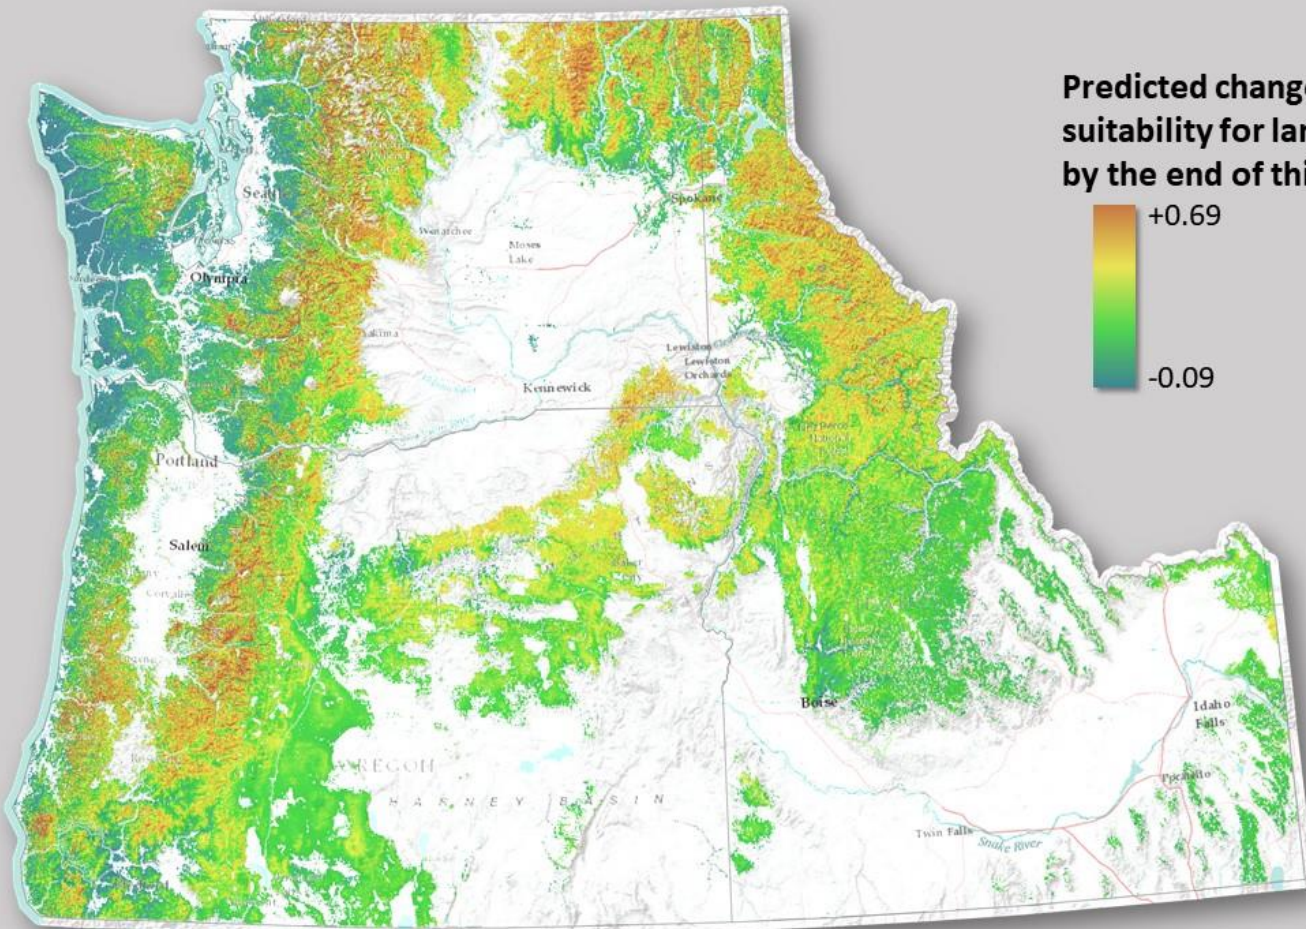

mid-century

end-century

Relative suitability for large wildfires

# Suitability for large wildfires

Predicted change in relative suitability for large wildfires by the end of this century

# Large west-side fires of the past

- **Year ~1700 fire episode:**
  - **>1 million acres on Olympic Peninsula,**
  - **3 to 10 million acres in western WA**

(Henderson et al. 1989)

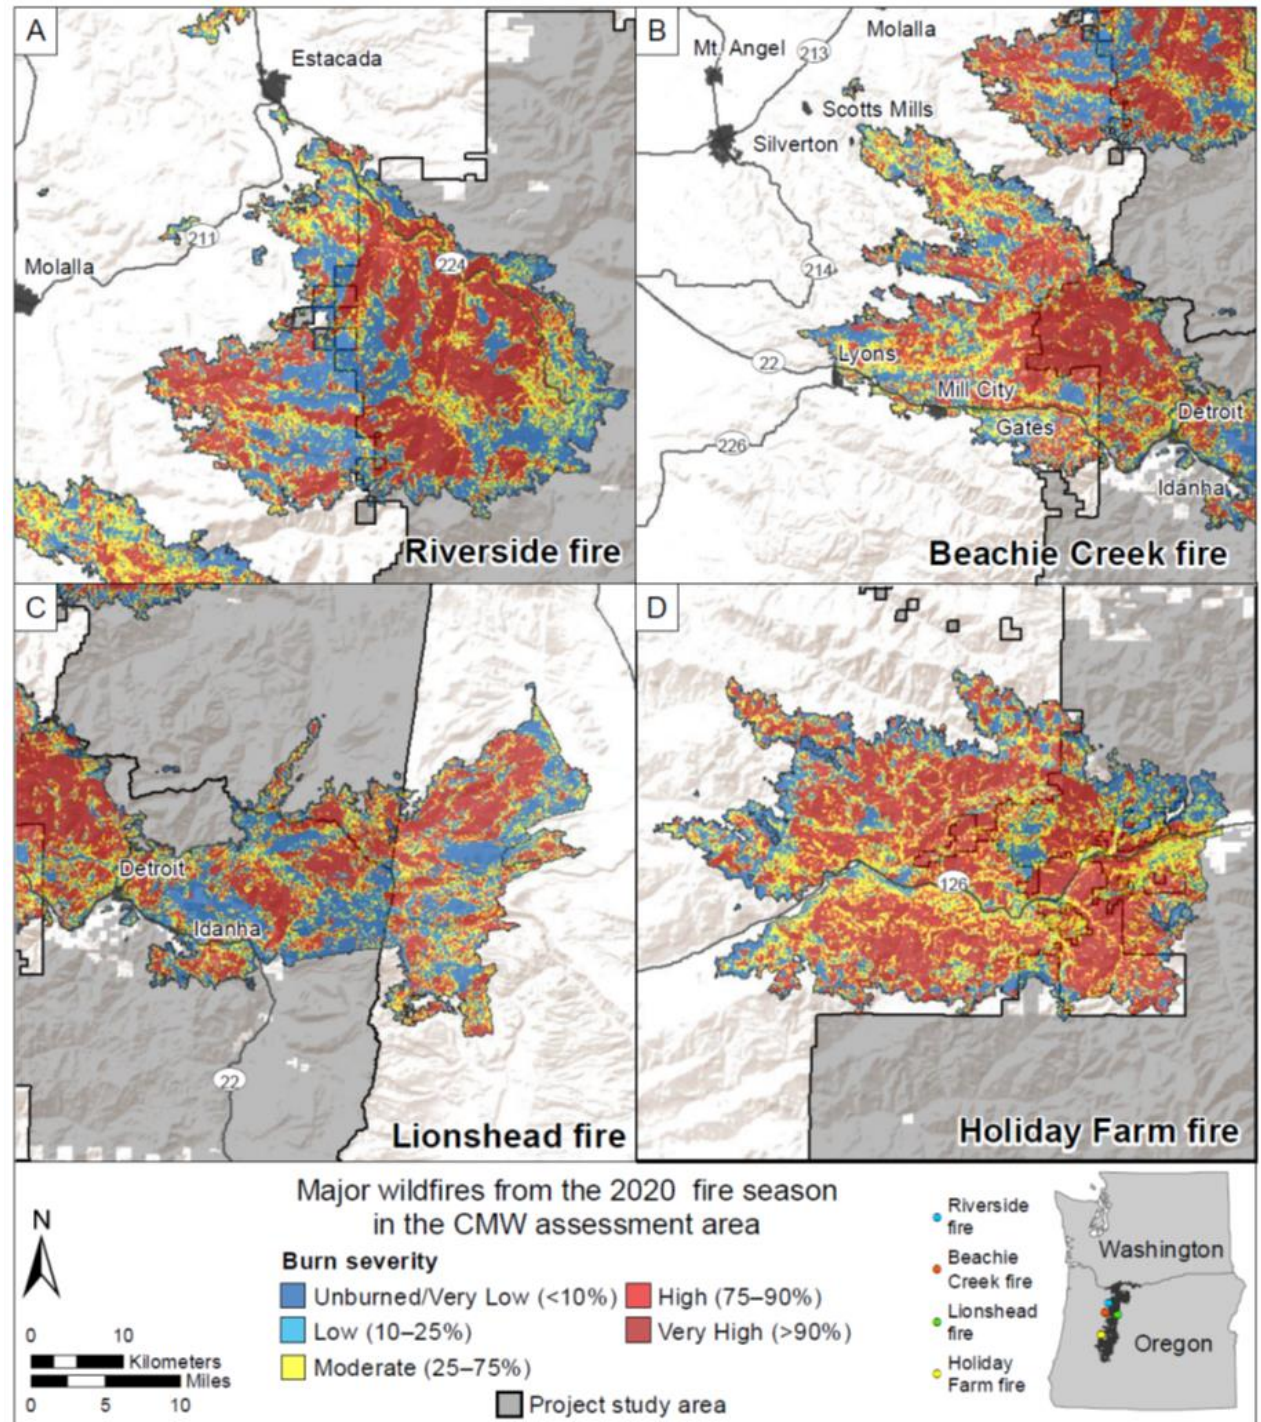

- **1902 Yacolt complex**
  - **>1 million acres**
  - (National Interagency Fire Center)
- **1933 Tillamook burn**
  - **350,000 acres**
  - (Kemp 1960)

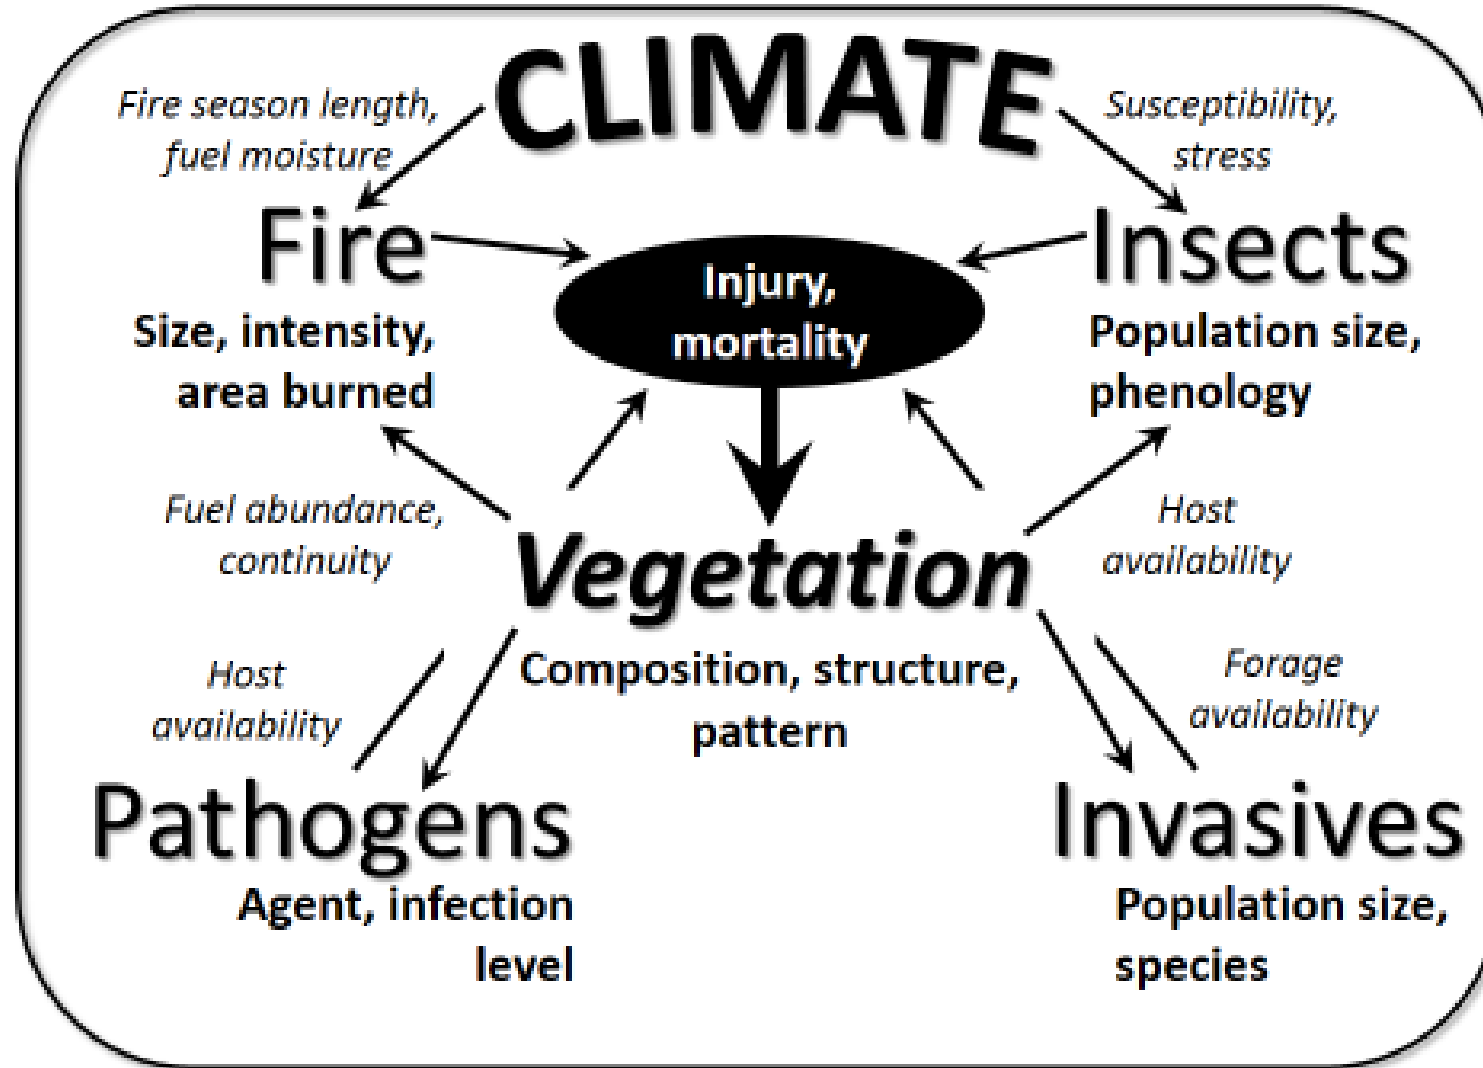

# 2020 Fires in Oregon

- Strong east winds were a key driver of fire spread.
- Fires were similar to east wind-driven events in the past.
- Event was consistent with what we might expect to occur more frequently with climate change

# Disturbances will interact

# What does this mean for forests in the Northwest and beyond?

# What does this mean for forests in the Pacific Northwest and beyond?

- Lower soil moisture will cause gradual changes in abundance and distribution of species; drought-tolerant species will be more competitive.
- Increased disturbance (wildfire, insect outbreaks) will facilitate vegetation change; younger forest age/structure.
- Increased non-native plant species will compete with native species.

**High severity “reburns” may occur before forests recover from the most recent high-severity fire**

# Large fires are creating larger and more homogeneous patches of stand-replacing fire

# Regeneration is very sensitive to climate

# Drought, bark beetle outbreaks, and fires will likely interact

**Forests will change in species composition and structure, and in some places will transition to non-forest.**

# Species sensitivity to climate change depends on:

- Shade tolerance
- Fire tolerance
- Drought tolerance
- Climatic tolerance
- Genetic plasticity
- Current abundance
- Level of stress
- Dispersal capability
- Adaptive capacity
